In some regions of Nicaragua, sorghum used to be the poor man’s crop. In recent years, more farmers are growing sorghum, instead of maize, in response to changes in the local climate. A participatory plant breeding programme was set up, looking to improve the sorghum varieties grown. Some varieties have now been registered. With scientists and farmers now working together, further activities are planned, such as selecting suitable bean and maize varieties.

Gilles Trouche, Henri Hocdé, Silvio Aguirre and Irma Ortega Sequeira

Back in 2002, a study carried out by different organisations in Madriz, a district in northern Nicaragua, showed that more and more farmers were growing sorghum instead of the main staple crop, maize. Farmers were also willing to talk about growing and eating sorghum, while only a few years ago this would have been equal to admitting they were very poor. The study showed that a large percentage of farmers now grow white-grain short-cycle sorghum varieties (locally known as sorgo tortillero), in addition to those growing the daylength-sensitive varieties (or millón) that are now restricted to the less fertile fields.

Most farmers remember when these changes started (the first major drought experienced in 1972), and therefore relate the change in their cropping systems to the changes they see in the weather. They also reported that these changes have mainly taken place without the help of the government’s extension services, or without involving NGO programmes. As sorghum was not a major national staple crop, most governmental development programmes focused on the production of maize or beans. But farmers feel that sorghum is a major crop in terms of food security, and therefore expressed their interest in improving the varieties they grow.

Participatory plant breeding

Responding to this, CIRAD (a French agricultural research centre), INTA (Nicaragua’s national agricultural research institute), and CIPRES (a local NGO), began implementing a participatory plant breeding programme. Running from 2002 until 2008, it is part of a larger project covering several countries in Central America. The programme focused on diversifying and improving the sorghum varieties so as to match the needs of resource-poor farmers in the dry areas. The research team involved breeders, farmers and extension workers. First they considered the introduction of improved inbred lines or varieties from Africa, representing a wide genetic diversity. Farmers tried them out in their fields and evaluated their agronomic performances and also their culinary qualities. Secondly, crosses were then made between the local varieties and those of African origin with complementary traits. The aim was to develop progenies which would better satisfy the local farmers’ requirements.

As a result of this process, farmers now grow new varieties of tortillero and millón sorghum presenting higher and more stable yields and other quality traits. One was officially registered in 2007 by a smallholder’s co-operative, and is now being disseminated in the area covering the south of Honduras and the north of Nicaragua. Known as ‘Blanco Tortillero’, this variety was originally developed in Burkina Faso, giving excellent results in the low-input cropping systems (see Box). Another new variety highly praised by farmers is ‘Coludo Nevada’. At least 10 other lines derived from the crosses formerly mentioned, are currently in the final evaluation stages before being released.

One of the most important results observed is the formation of a core group of farmer-breeders. All of them are capable of selecting plants and progenies, of evaluating varieties with their own criteria, and taking decisions together with researchers and NGO extensionists. A large number of men and women, both

New varieties

Tortillero sorghum ‘Blanco Tortillero’
• Improved line developed in Burkina Faso for drought and low soil fertility conditions.
• Excellent combination of earliness, adaptation and yield stability in conditions of abiotic stress (drought or high rainfall, low soil fertility) and grain quality.
• Registered in Nicaragua in 2007 by the co-operative COSENUP R.L. with the technical support of CIPRES, INTA and CIRAD and the financial support of FDN Norway and ACSUR Spain.
• Is now being diffused in the north of Nicaragua and south of Honduras.

Millón sorghum ‘Coludo Nevado’
• Daylength-sensitive landrace from Sudan.
• Drought-tolerant and high ratooning capacity after the dry season.
• Good productivity in the maize-sorghum intercropped systems and excellent grain quality for making tortillas.
• Rapid adoption in the dry hillsides in the north of Nicaragua.

New tortillero and millón lines derived from crosses with African progenitors
• Plant types responding better to the farmers’ preferences.
• Higher grain yield and forage quality.

many of them
are now also involved in evaluating and selecting new progenies
of maize and beans, and plan to be further involved in managing
trials for new varieties of sisal (Agave sisalana) and vegetables.

Strengthening farmer innovation systems
Farmers and technicians are also working together to improve

rainfall (as in 2007). Research is currently being done in order to

in getting a relatively stable grain and fodder production, even

in cases of severe drought (as happened in 2006) or excessive
rainfall (as in 2007). Research is currently being done in order to

optimise this practice, looking at the best date and stem height for
cutting the plants. The team is also interested in the development
and selection of lines with better ratooning ability. One of these is
ratooning in the second cropping season. Ratooning is a technique
where a crop is cut down to its base, leaving the roots and

new shoots to develop. In sorghum, this technique helps

in crops which ensure production in all climatic conditions.
Breeding new varieties through a participatory and decentralised

approach is a way for farmers to deal with uncertainty, and
for anticipating climatic change. In short, they are looking for

flexibility in their cropping systems; they do not want very

specialised cultivars, preferring varieties able to produce in any

weather conditions.

Etrangères for their help, and also all farmers involved in the participatory plant
breeding programme.

ILEIA has started to develop a new educational series that will
make LEISA principles and practices more understandable. It
is called Farming Matters. Eventually, Farming Matters will
be published as a series of modules to help educators and
field workers explain better why to practise more sustainable
agriculture, and to put it into a wider perspective.

Before we publish the series on paper, however, we will make
it available on-line as it develops. Our hope is that we can
partly develop the series on-line, seeking input from LEISA
practitioners and readers around the world to make sure that
the guide will be relevant to people in the field. Besides this,
field testing and access to the on-going developments will be
made available on CD-ROM to readers without access to the
internet.

The global version of Farming Matters will be developed in
English first, though many partners in the LEISA network may
eventually develop their own more regionally focused versions
in different languages.

Farming Matters approach: learning
We will explain the main principles behind LEISA, give ideas on
how to explain scientific concepts (with examples, illustrations
and clear definitions), and remind about the wider context of
farming (for example, looking at cultural, economic and political
factors in addition to the ecological principles). References
will be made to both local and scientific knowledge. Finally,
rather than giving recipes to solve problems, Farming Matters
will keep asking questions, to get people to reflect on the principles
within their own situation.

Help us develop a new educational series on LEISA principles

Look for notices about Farming Matters on the LEISA website (http://www.leisa.info) in the New Year!
